Let's Start!

HTML Inside the Programming Language Category

Learning Outcome:

Describe common simple incidents at work in a simple spoken or written situation with a supportive interlocutor. Assess the incident of data in the macrosystem processes, based on the data dictionary to consolidate intervening data, based in established parameters.

Can Do Statements:

- I can talk about programming languages and markup languages.
- I can discuss the reasons to consider HTML a programming language.
- I can list capabilities associated with a development language.

Ask your partner:

- Do you think applications have made people's lives easier? Why?
- What are the applications you use the most? Why?

Let's Explore!

Programming Language vs. Markup Language

Instructions: Read the text below.

Eric: To make a programming language and markup language comparison, we first have to know perfectly what they are.

Programming languages are different from markup languages because they are constructed languages divided into two components: the form and the meaning. Designers created them to give directions to a computer, allowing the creation of programs, which can control the conduct of the machine. These languages work through algorithms to write computer programs and even control computer external devices. Besides, they let humans communicate to machines.

On the other hand, markup languages are systems, which present information without instructions. To do so, you write documents with symbols and words encapsulated by tags, replacing long sentences with short instructions in digital media.

People never thought of HTML as a programming language; programmers usually considered that HTML didn't have many capabilities. This is why designers always considered HTML a markup language and during some time that was true, and there are people who think that HTML has capabilities normally associated to a development language. We can find some capabilities such as drag and drop, local storage or geolocation. Programmers often created some famous applications entirely with HTML and a few CSS. Do developers say those are not enough reasons to consider HTML a programming language? Actually, they do. However, something real is that, nowadays, programmers use HTML for the creation of applications, and that is a good reason to consider it a programming language.

Let's Practice!

Main Ideas about Programming and Mark up Languages.

Instructions: Underline all the incorrect words in the sentences. Write the corrected sentences on the lines provided.

1. A programming language is a formal symbol designers developed to give orders to a machine.

2. A markup language has encapsulated capabilities in tags.

3. The first programming languages came in conducts of punched cards or magnetic tapes.

Let's Practice!

Is HTML a Programming language or not?

Instructions: Classify the sentences by writing the number of the sentence in the correct category.

1. It tells the computer what to do.
2. It "marks up" data with tags to define its purpose on the website.
3. Developers use it for structural purposes, not functional.
4. It provides information to the browser to interpret.
5. It just tells the browser how to display elements.

HTML is a Programming language	HTML is not a Programming language

Extension Activity

Let's present Programming and Markup Languages.

Instructions: Complete the following steps. Fill in the Self-Assessment.

- Do some further research on programming languages.
- Create a poster which includes the following steps.
- Define with your own words Programming and Markup Languages.
- Make a list of examples for each language.
- Do you consider HTML a programming language? Why?
- Present your poster to your classmates.

Self-Assessment

Yes No

- I can identify the characteristics of a Programming and a Markup Language ☐ ☐
- I can classify different system languages into Programming or Markup according to its function. ☐ ☐
- I can explain my opinion about HTML. ☐ ☐
- I can demonstrate my knowledge about programming languages. ☐ ☐

Target Words

- comparison** (noun): the act of referring at two things or groups of things to say they are similar
e.g. To make a programming language and markup language comparison, we first have to know perfectly what they are.
- direction** (noun): an act of telling a person or a thing what to do and how to do it
e.g. Designers created them to give directions to a computer.
- conduct** (noun): the way a person or a thing behaves
e.g. Designers created them to give directions to a computer, allowing the creation of programs, which can control the conduct of the machine.
- symbols** (noun): a conventional sign used in writing
e.g. In markup languages you write document with symbols and words encapsulated by tags, replacing long sentences with short instructions in digital media.
- encapsulate** (verb): to enclose between two things
e.g. You write documents with symbols and words encapsulated by tags.
- capability** (noun): the potential to do something
e.g. We can find some capabilities such as drag and drop, local storage or geolocation.

Learning Points

Simple past Tense Statements with Frequency Adverbs

You use **simple past** when you want to describe events that end in a specific moment in the past.

When you use **simple past** you can use also **adverbs of frequency** in order to specify when an action takes place.

The **adverbs** can be placed at the beginning of the sentence, but are always after the verb **to be**.

Example:

- *They were never interested in a markup language.*

But most of the time adverbs are placed before the main verb in a sentence.
e.g. I always used HTML to create programs.

FREQUENCY	ADVERB
0%	Never
5%	Rarely
15%	Seldom
35%	Ocassionally
50%	Sometimes
60%	Frequently
70%	Normally
85%	Usually
100%	Always

Examples

- *HTML was always interesting as a markup language.*

Learning Points

Types of Markup Language.

There are three types of markup language.

The general categories of electronic markup are:

- The type of markup called **presentational** used by traditional word- processing systems or binary codes installed in a document text that create an effect in which content can be seeing while is being edited.
- The type of markup called **procedural** is installed in text to provide instructions for text process programs. This kind of markup allows authors to edit visible and directly the text.
- The **descriptive** markup is used to label document parts, some examples are HTML and XML. This markup encourages authors to write in a conceptually form not visually.
